

That's correct. The important point is that what visitors see on the internet is whatever the **authoritative nameservers** are serving, not necessarily what is displayed in a particular cPanel account.

In your case:

```
cPanel Zone Editor:  
firesafetylevyclearance.org.ng -> 102.68.84.170
```

but

```
Authoritative nameserver (ns1.mysecurecloudhost.com):  
firesafetylevyclearance.org.ng -> 65.181.113.151
```

This tells us one of the following is happening:

1. You're editing the DNS zone in the wrong cPanel account.
2. The domain is using a different DNS zone from the one you're editing.
3. The DNS changes were not saved or have not been applied on the authoritative nameserver.
4. The domain's nameservers point somewhere else.

Step 1: Check the Domain's Nameservers

Run:

Bash

```
whois firesafetylevyclearance.org.ng
```

or

Bash

```
dig NS firesafetylevyclearance.org.ng
```

You should see something similar to:

```
ns1.mysecurecloudhost.com  
ns2.mysecurecloudhost.com
```

If the nameservers are different, then you're editing DNS in the wrong place.

Step 2: Check What the Nameserver Is Serving

Run:

Bash

```
dig @ns1.mysecurecloudhost.com firesafetylevyclearance.org.ng A
```

If it still returns:

```
65.181.113.151
```

then the nameserver has not been updated.

Also check the second nameserver:

Bash

```
dig @ns2.mysecurecloudhost.com firesafetylevyclearance.org.ng A
```

If both return the old IP address, the authoritative DNS zone is definitely incorrect.

Step 3: Verify the DNS Zone File

If you have WHM or root access, inspect the zone file.

For example:

Bash

```
cat /var/named/firesafetylevyclearance.org.ng.db
```

or:

Bash

```
grep 102.68.84.170 /var/named/*
```

You should see something like:

```
firesafetylevyclearance.org.ng. IN A 102.68.84.170
```

If it still shows:

```
65.181.113.151
```

then the DNS zone file has not been updated.

Step 4: Check for DNS Cluster Synchronization

If the server uses a DNS cluster, the cPanel interface may show one value while another DNS server is actually serving the records.

Check whether:

- DNS clustering is enabled.
- The zone has synchronized successfully.
- The DNS service has been restarted.

In WHM, you can usually verify this under:

- DNS Functions
- DNS Cluster
- Synchronize DNS Records

Step 5: Clear Conflicting Records

Verify that only one A record exists for the root domain.

Correct:

```
A      @      102.68.84.170
CNAME  www    firesafetylevyclearance.org.ng
```

Incorrect examples:

```
A      @      65.181.113.151
A      @      102.68.84.170
```

or

```
A      firesafetylevyclearance.org.ng    65.181.113.151
```

If conflicting records exist, remove the old one.

Step 6: Check Propagation

After updating the authoritative nameserver, confirm with:

```
Bash
```

```
dig firesafetylevyclearance.org.ng A
```

and

Bash

```
nslookup firesafetylevyclearance.org.ng
```

You should see:

```
102.68.84.170
```

Conclusion

The problem is not DNS propagation. The authoritative nameserver itself is still publishing `65.181.113.151`. Until the DNS zone on the authoritative nameserver (`ns1.mysecurecloudhost.com`) is updated to `102.68.84.170`, the rest of the internet will continue to resolve the domain to the old IP address.

The DNS record must be corrected on the authoritative nameserver or in the DNS management system that controls it. Once that is done, propagation will occur normally.
